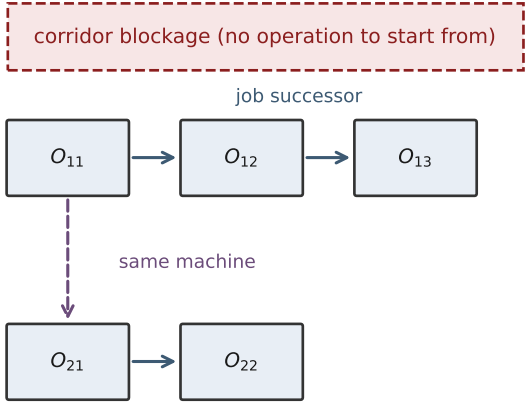
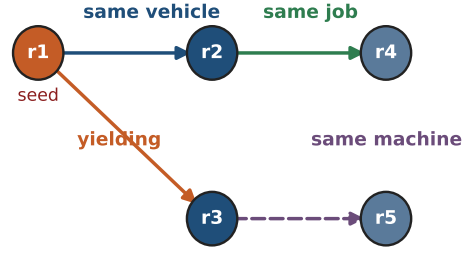
(a) operation-precedence graph G_T (vertex = operation)



$T_{\text{direct}} = \varnothing$

vertex set disjoint from the corridor occupancies

(b) reservation dependency graph G_R (vertex = corridor occupancy)



seed occupancies non-empty; successors collected along four edge kinds

the impact set is the transitive closure on this graph, not an operation neighbourhood

yielding (same corridor, different vehicles)
same-job successor
same-vehicle successor
same-machine successor
